NextSeason(4).zip
Zip Archive

This is the project after Cursor/Claude has implemented the rest of Phase 2. Please review it.

I'll review the zip as a code review: first map what changed, then inspect the Phase 2-related files, then call out concrete issues by severity without modifying anything.

I've got the project unpacked and the Phase 2 surface area is clear: search, detail, watchlist persistence, refresh/notifications, and tests. I'm checking now for correctness issues rather than style nits.

Thought for 1m 0s >

Reviewed. Overall: **this is solid work**. The architecture is still clean, the view models are testable, SwiftData is properly behind a repository, and the notification/refresh pieces are reasonably scoped.

I found **one important issue**:

High priority — background refresh can miss updates.

`WatchlistRefreshService.refreshAll()` asks TVMaze for only `.day` updates, but background refresh is best-effort and may not run every 12 hours. If iOS delays refresh for more than a day, the app could miss a TVMaze update entirely.

Relevant code:

```
<> Swift
updates = try await tvMaze.updatedShows(since: .day)
```

I'd change this to `.week` at minimum, or choose the window based on the oldest `lastCheckedAt`.

Other smaller notes:

Medium — notification authorization is requested only after adding a show.

That's fine for MVP, but there's no user-visible explanation before the system prompt. Later, you may want an onboarding-style explanation.

Medium — detail view reloads every time its task runs.

`ShowDetailView` creates the VM once, but still calls `load()` every `.task` execution. Not disastrous, just potentially extra network traffic.

Low — `deliver()` only accepts `.authorized`.

`requestAuthorizationIfNeeded()` treats `.provisional` and `.ephemeral` as allowed, but `deliver()` silently skips them. Probably not relevant unless you use provisional notifications.

Low — I couldn't run an actual Xcode build here.

This environment doesn't have `xcodebuild`, so this is a static review. Nothing obvious jumped out as a compile problem.

My recommendation: **fix the `.day` update-window issue before merging**. Everything else can reasonably wait.
